Communicated by Sheng Yu

The partial derivative automaton $\left(\mathcal{A}_{\mathrm{pd}}\right)$ is usually smaller than other nondeterministic finite automata constructed from a regular expression, and it can be seen as a quotient of the Glushkov automaton ( $\mathcal{A}_{\text {pos }}$ ). By estimating the number of regular expressions that have $\varepsilon$ as a partial derivative, we compute a lower bound of the average number of mergings of states in $\mathcal{A}_{\text {pos }}$ and describe its asymptotic behaviour. This depends on the alphabet size, $k$, and for growing $k$ 's its limit approaches half the number of states in $\mathcal{A}_{\text {pos }}$. The lower bound corresponds to consider the $\mathcal{A}_{\text {pd }}$ automaton for the marked version of the regular expression, i.e. where all its letters are made different. Experimental results suggest that the average number of states of this automaton, and of the $\mathcal{A}_{\mathrm{pd}}$ automaton for the unmarked regular expression, are very close to each other.

Keywords: Regular languages; regular expressions; partial derivatives; conversion between regular expressions and nondeterministic finite automata; analytic combinatorics; average case analysis.

## 1. Introduction

There are several well-known constructions to obtain nondeterministic finite automata from regular expressions. The worst case analysis of both the complexity of the conversion algorithms, and the size of the resulting automata, are well studied. However, for practical purposes, the average case analysis can provide much

[^0]more useful information. Recently, Nicaud [13] presented an average case study of the size of the Glushkov automata, proving that, on average, the number of transitions is linear in the size of the expression. This analysis was carried out using the framework of analytic combinatorics.

Following the same approach, in this paper we focus on the partial derivative automaton $\left(\mathcal{A}_{\mathrm{pd}}\right)$, which was introduced by Antimirov [2], and is a nondeterministic version of the Brzozowski automaton [3]. In order to have an inductive definition of the set of states of $\mathcal{A}_{\mathrm{pd}}$, we consider Mirkin's formulation of prebases. The equivalence of the two constructions, Mirkin's prebases and sets of partial derivatives, was pointed out by Champarnaud and Ziadi [4]. We briefly revisit Mirkin's algorithm, due to an inaccuracy in that presentation.

In 2002, Champarnaud and Ziadi [5] showed that the partial derivative automaton is a quotient of the Glushkov automaton. As such, the $\mathcal{A}_{\mathrm{pd}}$ automaton can be obtained from the $\mathcal{A}_{\text {pos }}$ automaton by merging states. The number of states in $\mathcal{A}_{\mathrm{pd}}$, which never exceeds the number of states in $\mathcal{A}_{\text {pos }}$, appears to be significantly smaller in practice. In this work we are particularly interested in measuring this difference. By estimating the number of regular expressions that have $\varepsilon$ as a partial derivative, we compute a lower bound for the average number of mergings of states in $\mathcal{A}_{\text {pos }}$, and study its asymptotic behaviour. This behaviour depends on the alphabet size, $k$, and its limit, for growing $k$ 's, approaches half the number of states in $\mathcal{A}_{\text {pos }}$. Our experimental results suggest that this lower bound is very close to the actual value.

## 2. Regular Expressions and Automata

In this section we briefly review some basic definitions about regular expressions and finite automata. For more details, we refer the reader to Kozen [9] or Sakarovitch [14].

Let $\Sigma=\left\{\sigma_{1}, \ldots, \sigma_{k}\right\}$ be an alphabet (set of letters) of size $k$. A word $w$ over $\Sigma$ is any finite sequence of letters. The empty word is denoted by $\varepsilon$. Let $\Sigma^{\star}$ be the set of all words over $\Sigma$. A language over $\Sigma$ is a subset of $\Sigma^{\star}$.

The left quotient of a language $L \subseteq \Sigma^{\star}$ by a word $w \in \Sigma^{\star}$ is the language $w^{-1} L=\left\{x \in \Sigma^{\star} \mid w x \in L\right\}$.

The set R of regular expressions over $\Sigma$ is defined by:

$$
\begin{equation*}
\alpha:=\emptyset|\varepsilon| \sigma_{1}|\cdots| \sigma_{k}|(\alpha+\alpha)|(\alpha \cdot \alpha) \mid \alpha^{\star} \tag{1}
\end{equation*}
$$

where the operator • (concatenation) is often omitted. The language $\mathcal{L}(\alpha)$ associated to $\alpha$ is inductively defined as follows: $\mathcal{L}(\emptyset)=\emptyset, \mathcal{L}(\varepsilon)=\{\varepsilon\}, \mathcal{L}(\sigma)=\{\sigma\}$ for $\sigma \in \Sigma$, $\mathcal{L}((\alpha+\beta))=\mathcal{L}(\alpha) \cup \mathcal{L}(\beta), \mathcal{L}((\alpha \cdot \beta))=\mathcal{L}(\alpha) \cdot \mathcal{L}(\beta)$, and $\mathcal{L}\left(\alpha^{\star}\right)=\mathcal{L}(\alpha)^{\star}$. The size $|\alpha|$ of $\alpha \in \mathrm{R}$ is the number of symbols in $\alpha$ (parentheses not counted); the alphabetic size $|\alpha|_{\Sigma}$ is its number of letters. We define $\varepsilon(\alpha)$ by $\varepsilon(\alpha)=\varepsilon$ if $\varepsilon \in \mathcal{L}(\alpha)$, and $\varepsilon(\alpha)=\emptyset$ otherwise. If two regular expressions $\alpha$ and $\beta$ are syntactically identical we write $\alpha \equiv \beta$. Two regular expressions $\alpha$ and $\beta$ are equivalent if $\mathcal{L}(\alpha)=\mathcal{L}(\beta)$, and we write $\alpha=\beta$. With this interpretation, the algebraic structure ( $\mathrm{R},+, \cdot, \emptyset, \varepsilon$ ) constitutes an idempotent semiring, and with the unary operator $\star$, a Kleene algebra.

A nondeterministic automaton (NFA) is a quintuple $\mathcal{A}=\left(Q, \Sigma, \delta, q_{0}, F\right)$, where $Q$ is a finite set of states, $\Sigma$ is the alphabet, $\delta \subseteq Q \times \Sigma \times Q$ the transition relation, $q_{0}$ the initial state, and $F \subseteq Q$ the set of final states. The size of a $\mathcal{A}$ is $|Q|+|\delta|$. For $q \in Q$ and $\sigma \in \Sigma$, we denote the set $\{p \mid(q, \sigma, p) \in \delta\}$ by $\delta(q, \sigma)$, and we can extend this notation to $w \in \Sigma^{\star}$, and to $R \subseteq Q$. The language accepted by $\mathcal{A}$ is $\mathcal{L}(\mathcal{A})=\left\{w \in \Sigma^{\star} \mid \delta\left(q_{0}, w\right) \cap F \neq \emptyset\right\}$.

## 3. The Partial Derivative Automaton

Let $S \cup\{\beta\}$ be a set of regular expressions. Then $S \odot \beta=\{\alpha \beta \mid \alpha \in S\}$ if $\beta \notin\{\emptyset, \varepsilon\}$, $S \odot \emptyset=\emptyset$, and $S \odot \varepsilon=S$. Analogously, one defines $\beta \odot S$.

For a regular expression $\alpha$ and a letter $\sigma \in \Sigma$, the set $\partial_{\sigma}(\alpha)$ of partial derivatives of $\alpha$ w.r.t. $\sigma$ is defined inductively as follows:

$$
\begin{array}{ll}
\partial_{\sigma}(\emptyset)=\partial_{\sigma}(\varepsilon)=\emptyset & \partial_{\sigma}(\alpha+\beta)=\partial_{\sigma}(\alpha) \cup \partial_{\sigma}(\beta) \\
\partial_{\sigma}\left(\sigma^{\prime}\right)= \begin{cases}\{\varepsilon\} \text { if } \sigma^{\prime} \equiv \sigma & \emptyset \\
\text { otherwise }\end{cases} & \partial_{\sigma}(\alpha \beta)
\end{array}= \begin{cases}\partial_{\sigma}(\alpha) \odot \beta \cup \partial_{\sigma}(\beta) \text { if } \varepsilon(\alpha)=\varepsilon \\
\partial_{\sigma}(\alpha) \odot \beta & \text { otherwise. }\end{cases}
$$

This definition can be extended to sets of regular expressions, to words, and to languages by: given $\alpha \in \mathrm{R}$ and $\sigma \in \Sigma, \partial_{\sigma}(S)=\cup_{\beta \in S} \partial_{\sigma}(\beta)$ for $S \subseteq \mathrm{R} ; \partial_{\varepsilon}(\alpha)=\{\alpha\}$, $\partial_{w \sigma}(\alpha)=\partial_{\sigma}\left(\partial_{w}(\alpha)\right)$ for $w \in \Sigma^{\star}$; and $\partial_{L}(\alpha)=\cup_{w \in L} \partial_{w}(\alpha)$ for $L \subseteq \Sigma^{\star}$. Trivially extending the notion of language represented by a regular expression to sets of regular expressions, one has that $L\left(\partial_{w}(\alpha)\right)=w^{-1} L(\alpha)$, for any $w \in \Sigma^{\star}$. The set of partial derivatives of $\alpha,\left\{\partial_{w}(\alpha) \mid w \in \Sigma^{\star}\right\}$, is denoted by $\operatorname{PD}(\alpha)$.

The partial derivative automaton $\mathcal{A}_{\mathrm{pd}}(\alpha)$, introduced by Antimirov, is defined by

$$
\mathcal{A}_{\mathrm{pd}}(\alpha)=\left(\mathrm{PD}(\alpha), \Sigma, \delta_{p d}, \alpha,\{q \in \operatorname{PD}(\alpha) \mid \varepsilon(q)=\varepsilon\}\right),
$$

where $\delta_{p d}(q, \sigma)=\partial_{\sigma}(q)$, for all $q \in \operatorname{PD}(\alpha)$ and $\sigma \in \Sigma$.

Proposition 1 (Antimirov) $\mathcal{L}\left(\mathcal{A}_{\mathrm{pd}}(\alpha)\right)=\mathcal{L}(\alpha)$.

Example 2. Throughout the paper we will use the regular expression

$$
\tau=(a+b)\left(a^{\star}+b a^{\star}+b^{\star}\right)^{\star}
$$

given by Ilie and Yu [8]. This example illustrates perfectly the purpose of our constructions in Section 5.1. For $\tau$ one has, $\operatorname{PD}(\tau)=\left\{\tau, \tau_{1}, \tau_{2}, \tau_{3}\right\}$, where $\tau_{1}=$ $\left(a^{\star}+b a^{\star}+b^{\star}\right)^{\star}, \tau_{2}=a^{\star} \tau_{1}$ and $\tau_{3}=b^{\star} \tau_{1}$. The corresponding automaton $\mathcal{A}_{\mathrm{pd}}(\tau)$ is the following:

### 3.1. Mirkin's formulation

Champarnaud and Ziadi [4] showed that partial derivatives and Mirkin's prebases [12] lead to identical constructions of nondeterministic automata. In order to do this, they proposed a recursive algorithm for computing the Mirkin's prebases. However, that algorithm has an inaccuracy for the concatenation rule. Here, we give the corrected version of the algorithm.

Let $\alpha_{0}$ be a regular expression. A set $\pi\left(\alpha_{0}\right)=\left\{\alpha_{1}, \ldots, \alpha_{n}\right\}$, where $\alpha_{1}, \ldots, \alpha_{n}$ are non-empty regular expressions, is called a support of $\alpha_{0}$ if, for $i=0, \ldots, n$, there are $\alpha_{i l} \in \mathrm{R}(l=1, \ldots, k)$, linear combinations of the elements in $\pi\left(\alpha_{0}\right)$, such that $\alpha_{i}=\sigma_{1} \cdot \alpha_{i 1}+\ldots+\sigma_{k} \cdot \alpha_{i k}+\varepsilon\left(\alpha_{i}\right)$, where, as above, $\Sigma=\left\{\sigma_{1}, \ldots, \sigma_{k}\right\}$ is the considered alphabet. If $\pi(\alpha)$ is a support of $\alpha$, then the set $\pi(\alpha) \cup\{\alpha\}$ is called a prebase of $\alpha$.

Proposition 3 (Mirkin/Champarnaud\&Ziadi) Let $\alpha$ be a regular expression. Then the set $\pi(\alpha)$, inductively defined by ${ }^{\text {a }}$

$$
\begin{aligned}
\pi(\emptyset) & =\emptyset & \pi(\alpha+\beta) & =\pi(\alpha) \cup \pi(\beta) \\
\pi(\varepsilon) & =\emptyset & \pi(\alpha \beta) & =\pi(\alpha) \odot \beta \cup \pi(\beta) \\
\pi(\sigma) & =\{\varepsilon\} & \pi\left(\alpha^{\star}\right) & =\pi(\alpha) \odot \alpha^{\star},
\end{aligned}
$$

is a support of $\alpha$.
In his original paper Mirkin showed that $|\pi(\alpha)| \leq|\alpha|_{\Sigma}$. Furthermore, Champarnaud and Ziadi established that $\operatorname{PD}(\alpha)=\pi(\alpha) \cup\{\alpha\}$. Thus $|\operatorname{PD}(\alpha)| \leq|\alpha|_{\Sigma}+1$.

### 3.2. The Glushkov automaton

To review the definition of the Glushkov automaton, let $\operatorname{Pos}(\alpha)=\left\{1,2, \ldots,|\alpha|_{\Sigma}\right\}$ be the set of positions for $\alpha \in \mathrm{R}$, and let $\operatorname{Pos}_{0}(\alpha)=\operatorname{Pos}(\alpha) \cup\{0\}$. We consider the expression $\bar{\alpha}$ obtained by marking each letter with its position in $\alpha$, i.e. $\mathcal{L}(\bar{\alpha}) \in \bar{\Sigma}^{\star}$ where $\bar{\Sigma}=\left\{\sigma^{i}|\sigma \in \Sigma, 1 \leq i \leq|\alpha| \Sigma\}\right.$. The same notation is used to remove the markings, i.e., $\overline{\bar{\alpha}}=\alpha$. For $\alpha \in \mathrm{R}$ and $i \in \operatorname{Pos}(\alpha)$, let

$$
\begin{array}{ll}
\operatorname{first}(\alpha) & =\left\{i \mid \exists w \in \bar{\Sigma}^{\star}, \sigma^{i} w \in \mathcal{L}(\bar{\alpha})\right\}, \\
\text { last }(\alpha) & =\left\{i \mid \exists w \in \bar{\Sigma}^{\star}, w \sigma^{i} \in \mathcal{L}(\bar{\alpha})\right\} \text { and } \\
\text { follow }(\alpha, i) & =\left\{j \mid \exists u, v \in \bar{\Sigma}^{\star}, u \sigma^{i} \sigma^{j} v \in \mathcal{L}(\bar{\alpha})\right\} .
\end{array}
$$

${ }^{\text {a }}$ The rule for concatenation in [4] is $\pi(\alpha \beta)=\pi(\alpha) \odot \beta \cup \varepsilon(\alpha) \odot \pi(\beta)$, which, e.g., produces $\pi(a b)=\{b\}$. But, $\operatorname{PD}(a b)=\{a b, b, \varepsilon\}$, thus $\pi(a b) \supseteq\{b, \varepsilon\}$.

The Glushkov automaton for $\alpha$ is $\mathcal{A}_{\text {pos }}(\alpha)=\left(\operatorname{Pos}_{0}(\alpha), \Sigma, \delta_{\text {pos }}, 0, F\right)$, with

$$
\delta_{\text {pos }}=\left\{\left(0, \overline{\sigma^{j}}, j\right) \mid j \in \operatorname{first}(\alpha)\right\} \cup\left\{\left(i, \overline{\sigma^{j}}, j\right) \mid j \in \text { follow }(\alpha, i)\right\}
$$

and $F=\operatorname{last}(\alpha) \cup\{0\}$ if $\varepsilon(\alpha)=\varepsilon$, and $F=\operatorname{last}(\alpha)$, otherwise. We note that the number of states of $\mathcal{A}_{\text {pos }}(\alpha)$ is exactly $|\alpha|_{\Sigma}+1$. Champarnaud and Ziadi [5] showed that the partial derivative automaton is a quotient of the Glushkov automaton. The right-invariant equivalence relation used in showing that the $\mathcal{A}_{\mathrm{pd}}$ is a quotient of $\mathcal{A}_{\text {pos }}$ relates the sets first and last with (multi-)sets of partial derivatives w.r.t a letter.

Example 4. The Glushkov automaton for $\tau, \mathcal{A}_{\text {pos }}(\tau)$, is the following:

## 4. Generating Functions and Analytic Methods

A combinatorial class C is a set of objects on which a non-negative integer function (size) $|\cdot|$ is defined, and such that for each $n \geq 0$, the number of objects of size $n$, $c_{n}$, is finite. The generating function $C(z)$ of C is the formal power series

$$
C(z)=\sum_{c \in \mathrm{C}} z^{|c|}=\sum_{n=0}^{\infty} c_{n} z^{n} .
$$

The symbolic method (Flajolet and Sedgewick [7]) is a framework that allows the construction of a combinatorial class C in terms of simpler ones, $\mathrm{B}_{1}, \ldots, \mathrm{~B}_{n}$, by means of specific operations, and such that the generating function $C(z)$ of C is a function of the generating functions $B_{i}(z)$ of $\mathrm{B}_{i}$, for $1 \leq i \leq n$. For example, given two disjoint combinatorial classes A and B , with generating functions $A(z)$ and $B(z)$, respectively, the union $A \cup B$ is a combinatorial class whose generating function is $A(z)+B(z)$. Other usual admissible operations are the cartesian product and the Kleene closure.

Usually multivariate generating functions are used in order to obtain estimates about the asymptotic behaviour of various parameters associated to combinatorial classes. Here, however, we consider cost generating functions, as Nicaud [13] did. Given $f: \mathrm{C} \rightarrow \mathbb{N}$, the cost generating function $F(z)$ of C associated to $f$ is

$$
F(z)=\sum_{c \in \mathrm{C}} f(c) z^{|c|}=\sum_{n \geq 0} f_{n} z^{n} \text {, with } f_{n}=\sum_{c \in \mathrm{C},|c|=n} f(c) \text {. }
$$

With $\left[z^{n}\right] F(z)$ denoting the coefficient of $z^{n}$, the average value of $f$ for the uniform distribution on the elements of size $n$ of C is, obviously,

$$
\mu_{n}(\mathrm{C}, f)=\frac{\left[z^{n}\right] F(z)}{\left[z^{n}\right] C(z)}
$$

For the regular expressions given in (1), but without $\emptyset$, an average case analysis of different descriptional measures, including the number of letters or the size of its Glushkov automaton, has been presented by Nicaud.

In particular, it was shown that, for the generating function for regular expressions, $R_{k}(z)$, which satisfies

$$
\begin{equation*}
R_{k}(z)=\frac{1-z-\sqrt{\Delta_{k}(z)}}{4 z}, \text { where } \Delta_{k}(z)=1-2 z-(7+8 k) z^{2} \tag{2}
\end{equation*}
$$

one has

$$
\begin{equation*}
\left[z^{n}\right] R_{k}(z) \sim \frac{\sqrt{2\left(1-\rho_{k}\right)}}{8 \rho_{k} \sqrt{\pi}} \rho_{k}^{-n} n^{-3 / 2}, \text { where } \rho_{k}=\frac{1}{1+\sqrt{8 k+8}} \tag{3}
\end{equation*}
$$

Here $\left[z^{n}\right] R_{k}(z)$ is the number of regular expressions $\alpha$ with $|\alpha|=n$.
Nicaud also showed that the cost generating function for the number of letters in an element $\alpha \in \mathrm{R}$ is

$$
\begin{equation*}
L_{k}(z)=\frac{k z}{\sqrt{\Delta_{k}(z)}} \tag{4}
\end{equation*}
$$

and satisfies

$$
\begin{equation*}
\left[z^{n}\right] L_{k}(z) \sim \frac{k \rho_{k}}{\sqrt{\pi\left(2-2 \rho_{k}\right)}} \rho_{k}^{-n} n^{-1 / 2} \tag{5}
\end{equation*}
$$

From this he deduced that

$$
\begin{equation*}
\frac{\left[z^{n}\right] L_{k}(z)}{\left[z^{n}\right] R_{k}(z)} \sim \frac{4 k \rho_{k}^{2}}{1-\rho_{k}} n \tag{6}
\end{equation*}
$$

For $k=2$ this results in approximately $0.277 n$ (and not $0.408 n$, as stated by Nicaud), and it is easy to see that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{4 k \rho_{k}^{2}}{1-\rho_{k}} \nearrow \frac{1}{2} \tag{7}
\end{equation*}
$$

This means that the average number of letters in a regular expression grows to about half its size, for large alphabets. In particular, for $k=10,100,1000$ we have $\frac{4 k \rho_{k}^{2}}{1-\rho_{k}}=0.467,0.485,0.494$, respectively.

### 4.1. Analytic asymptotics

Generating functions can be seen as complex analytic functions, and the study of their behaviour around their dominant singularities gives us access to the asymptotic form of their coefficients. We refer the reader to Flajolet and Sedgewick for an extensive study on this topic. Here we only state the propositions and lemmas used in this paper. Let $R>1$ and $0<\phi<\pi / 2$ be two real numbers, the domain $\Delta(\phi, R)$ at $z=\xi$ is $\Delta(\phi, R)=\{z \in \mathbb{C}| | z \mid<R, z \neq \xi$, and $|\operatorname{Arg}(z-\xi)|>\phi\}$, where $\operatorname{Arg}(z)$ denotes the argument of $z \in \mathbb{C}$. A domain is a $\Delta$-domain at $\xi$ if it is a $\Delta(\phi, R)$ at $\xi$ for some $R$ and $\phi$. The generating functions we consider have always a unique dominant singularity, and satisfy one of the two conditions of the following proposition, given by Nicaud.

Proposition 5. Let $f(z)$ be a function that is analytic in some $\Delta$-domain at $\rho \in \mathbb{R}^{+}$.
(1) If at the intersection of a neighborhood of $\rho$ and its $\Delta$-domain,

$$
f(z)=a-b \sqrt{1-z / \rho}+o(\sqrt{1-z / \rho}), \text { with } a, b \in \mathbb{R}, b \neq 0
$$

then $\left[z^{n}\right] f(z) \sim \frac{b}{2 \sqrt{\pi}} \rho^{-n} n^{-3 / 2}$.
(2) If at the intersection of a neighborhood of $\rho$ and its $\Delta$-domain,

$$
f(z)=\frac{a}{\sqrt{1-z / \rho}}+o\left(\frac{1}{\sqrt{1-z / \rho}}\right), \text { with } a \in \mathbb{R}, \text { and } a \neq 0
$$

then $\left[z^{n}\right] f(z) \sim \frac{a}{\sqrt{\pi}} \rho^{-n} n^{-1 / 2}$.
The following straightforward lemma was used throughout our analytic computations.

Lemma 6. If $f(z)$ is an entire function with $\lim _{z \rightarrow \rho} f(z)=a$ and $r \in \mathbb{R}$, then

$$
f(z)(1-z / \rho)^{r}=a(1-z / \rho)^{r}+o\left((1-z / \rho)^{r}\right)
$$

## 5. The Average Number of State Mergings

### 5.1. Regular expressions with $\varepsilon$ as a partial derivative

Since $\mathcal{A}_{\mathrm{pd}}(\alpha)$ is a quotient of the Glushkov automaton, we know that it has at most $|\alpha|_{\Sigma}+1$ states. But this upper bound is reached if and only if, at every step during the computation of $\pi(\alpha)$, all unions are disjoint. There are however two cases in which this clearly does not happen. Whenever $\varepsilon \in \pi(\beta) \cap \pi(\gamma)$,

$$
\begin{equation*}
|\pi(\beta+\gamma)|=|\pi(\beta) \cup \pi(\gamma)| \leq|\pi(\beta)|+|\pi(\gamma)|-1 \tag{8}
\end{equation*}
$$

and also

$$
\begin{align*}
\left|\pi\left(\beta \gamma^{\star}\right)\right|=\left|\pi(\beta) \odot \gamma^{\star} \cup \pi\left(\gamma^{\star}\right)\right| & =\left|\pi(\beta) \odot \gamma^{\star} \cup \pi(\gamma) \odot \gamma^{\star}\right| \\
& \leq|\pi(\beta)|+|\pi(\gamma)|-1 . \tag{9}
\end{align*}
$$

In this section we will estimate the number of non-disjoint unions formed during the computation of $\pi(\alpha)$ that are due to either one of the above cases. This corresponds to the merging of states in the Glushkov automaton. Notice that there might be additional mergings resulting from other identical elements in the support of the regular expressions. Therefore our estimation is only a lower bound of the actual number of state mergings, that turns out to be surprisingly tight as shown in Section 6.

Example 7. In order to illustrate the effect of $\varepsilon$ being a partial derivative of a subexpression, we consider the marked version of $\tau$, $\bar{\tau}=\left(a_{1}+b_{2}\right)\left(a_{3}^{\star}+b_{4} a_{5}^{\star}+b_{6}^{\star}\right)^{\star}$. In $\mathcal{A}_{\text {pos }}(\tau)$ each position corresponds to a state. Now, note that, for instance, one has

$$
\pi\left(a_{1}+b_{2}\right)=\pi\left(a_{1}\right) \cup \pi\left(b_{2}\right)=\{\varepsilon\} \cup\{\varepsilon\}=\{\varepsilon\}
$$

and

$$
\pi\left(b_{4} a_{5}^{\star}\right)=\pi\left(b_{4}\right) \odot a_{5}^{\star} \cup \pi\left(a_{5}\right) \odot a_{5}^{\star}=\{\varepsilon\} \odot a_{5}^{\star} \cup\{\varepsilon\} \odot a_{5}^{\star} .
$$

These two cases originate the mergings of states 1 and 2 , as well as 4 and 5 of $\mathcal{A}_{\text {pos }}(\tau)$.
There is another state merging that is due to neither of the above cases. In fact,

$$
\pi\left(a_{3}^{\star}+b_{4} a_{5}^{\star}\right)=\pi\left(a_{3}\right) \odot a_{3}^{\star} \cup \pi\left(b_{4}\right) \odot a_{5}^{\star}=\{\varepsilon\} \odot a_{3}^{\star} \cup\{\varepsilon\} \odot a_{5}^{\star} .
$$

Since the $\mathcal{A}_{\mathrm{pd}}(\tau)$ is computed for the unmarked $\tau$, there is also the merging of states 3 and 4. This is not the case for $\mathcal{A}_{\mathrm{pd}}(\bar{\tau})$, as can be seen in the following diagrams:

$$
\mathcal{A}_{\mathrm{pd}}(\tau)
$$

$\mathcal{A}_{\mathrm{pd}}(\bar{\tau})$

As this example suggests, the mergings of states that we consider in the computation of the lower bound correspond to mergings that arise when obtaining $\mathcal{A}_{\mathrm{pd}}(\bar{\alpha})$ from $\mathcal{A}_{\text {pos }}(\alpha)$.

From now on, $\alpha$ will denote regular expressions given in (1), but without $\emptyset$, and its generating function, $R_{k}(z)$ is given by (2). As mentioned, the number of
mergings for an expression $\alpha$ depends on the number of subexpressions with $\varepsilon$ in its support. We will estimate this number first. The grammar

$$
\alpha_{\pi_{\varepsilon}}:=\sigma \in \Sigma\left|\alpha_{\pi_{\varepsilon}}+\alpha\right| \alpha_{\overline{\pi_{\varepsilon}}}+\alpha_{\pi_{\varepsilon}}\left|\alpha \cdot \alpha_{\pi_{\varepsilon}}\right| \alpha_{\pi_{\varepsilon}} \cdot \varepsilon
$$

generates the set of regular expressions for which $\varepsilon \in \pi\left(\alpha_{\pi_{\varepsilon}}\right)$, that is denoted by $\mathrm{R}_{\pi_{\varepsilon}}$. The remaining regular expressions, that are not generated by this grammar, are denoted by $\alpha_{\overline{\pi_{\varepsilon}}}$.
The generating function for $\mathrm{R}_{\pi_{\varepsilon}}, R_{\pi_{\varepsilon}, k}(z)$, satisfies

$$
\begin{aligned}
R_{\pi_{\varepsilon}, k}(z)= & k z+z R_{\pi_{\varepsilon}, k}(z) R_{k}(z)+z\left(R_{k}(z)-R_{\pi_{\varepsilon}, k}(z)\right) R_{\pi_{\varepsilon}, k}(z) \\
& +z R_{k}(z) R_{\pi_{\varepsilon}, k}(z)+z^{2} R_{\pi_{\varepsilon}, k}(z),
\end{aligned}
$$

which is equivalent to

$$
z R_{\pi_{\varepsilon}, k}(z)^{2}-\left(z^{2}+3 z R_{k}(z)-1\right) R_{\pi_{\varepsilon}, k}(z)-k z=0
$$

and from which one gets

$$
\begin{equation*}
R_{\pi_{\varepsilon}, k}(z)=\frac{\left(z^{2}+3 z R_{k}(z)-1\right)+\sqrt{\left(z^{2}+3 z R_{k}(z)-1\right)^{2}+4 k z^{2}}}{2 z} . \tag{10}
\end{equation*}
$$

One has

$$
\begin{equation*}
8 z R_{\pi_{\varepsilon}, k}(z)=-b(z)-3 \sqrt{\Delta_{k}(z)}+\sqrt{a_{k}(z)+6 b(z) \sqrt{\Delta_{k}(z)}+9 \Delta_{k}(z)} \tag{11}
\end{equation*}
$$

with

$$
\begin{align*}
& a_{k}(z)=16 z^{4}-24 z^{3}+(64 k+1) z^{2}+6 z+1  \tag{12}\\
& b(z)=-4 z^{2}+3 z+1
\end{align*}
$$

and $\Delta_{k}(z)$ as in (2). Using the binomial theorem, one easily sees that

$$
\begin{aligned}
\sqrt{a_{k}(z)+6 b(z) \sqrt{\Delta_{k}(z)}+9 \Delta_{k}(z)} & =\sqrt{a_{k}(z)}\left(1+6 \frac{b(z)}{a_{k}(z)} \sqrt{\Delta_{k}(z)}+\frac{9}{a_{k}(z)} \Delta_{k}(z)\right)^{\frac{1}{2}} \\
& =\sqrt{a_{k}(z)}+3 \frac{b(z)}{\sqrt{a_{k}(z)}} \sqrt{\Delta_{k}(z)}+o\left(\Delta_{k}(z)^{\frac{1}{2}}\right),
\end{aligned}
$$

and therefore

$$
8 z R_{\pi_{\varepsilon}, k}(z)=-b(z)+\sqrt{a_{k}(z)}+3\left(\frac{b(z)}{\sqrt{a_{k}(z)}}-1\right) \sqrt{\Delta_{k}(z)}+o\left(\Delta_{k}(z)^{\frac{1}{2}}\right) .
$$

Using the fact that

$$
\sqrt{\Delta_{k}(z)}=\sqrt{(7+8 k) \rho_{k}\left(z-\bar{\rho}_{k}\right)} \sqrt{1-z / \rho_{k}}
$$

and that

$$
\sqrt{(7+8 k) \rho_{k}\left(\rho_{k}-\bar{\rho}_{k}\right)}=\sqrt{2-2 \rho_{k}},
$$

together with Proposition 1 in [13] and Lemma 6 above, one gets

$$
\begin{equation*}
\left[z^{n}\right] R_{\pi_{\varepsilon}, k}(z) \sim \frac{3}{16 \sqrt{\pi}}\left(1-\frac{b\left(\rho_{k}\right)}{\sqrt{a_{k}\left(\rho_{k}\right)}}\right) \sqrt{2\left(1-\rho_{k}\right)} \rho_{k}^{-(n+1)} n^{-3 / 2} \tag{13}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\frac{\left[z^{n}\right] R_{\pi_{\varepsilon}, k}(z)}{\left[z^{n}\right] R_{k}(z)} \sim \frac{3}{2}\left(1-\frac{b\left(\rho_{k}\right)}{\sqrt{a_{k}\left(\rho_{k}\right)}}\right) . \tag{14}
\end{equation*}
$$

Note that $\lim _{k \rightarrow \infty} \rho_{k}=0, \lim _{k \rightarrow \infty} a_{k}\left(\rho_{k}\right)=9$ and $\lim _{k \rightarrow \infty} b\left(\rho_{k}\right)=1$, and so the asymptotic ratio of regular expressions with $\varepsilon$ as a derivative approaches 1 as $k \rightarrow \infty$.

### 5.2. The generating function of mergings

Let $i(\alpha)$ be the number of non-disjoint unions appearing, due to (8) or (9), during the computation of $\pi(\alpha), \alpha \in \mathrm{R}$. These correspond to state mergings in Glushkov automata. Splitting the regular expressions into the disjoint classes $\alpha_{\pi_{\varepsilon}}$ and $\alpha_{\overline{\pi_{\varepsilon}}}$, $i(\alpha)$ verifies

$$
\begin{aligned}
i(\varepsilon) & =0 \\
i(\sigma) & =0 \\
i\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\pi_{\varepsilon}}\right) & =i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\alpha_{\pi_{\varepsilon}}\right)+1 \\
i\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\overline{\pi_{\varepsilon}}}\right) & =i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\alpha_{\overline{\pi_{\varepsilon}}}\right) \\
i\left(\alpha_{\overline{\pi_{\varepsilon}}}+\alpha\right) & =i\left(\alpha_{\overline{\pi_{\varepsilon}}}\right)+i(\alpha) \\
i\left(\alpha_{\pi_{\varepsilon}} \cdot \alpha_{\pi_{\varepsilon}}^{\star}\right) & =i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\alpha_{\pi_{\varepsilon}}\right)+1 \\
i\left(\alpha_{\pi_{\varepsilon}} \cdot \overline{\alpha_{\pi_{\varepsilon}}^{\star}}\right) & =i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\overline{\alpha_{\pi_{\varepsilon}}^{\star}}\right) \\
i\left(\alpha_{\overline{\pi_{\varepsilon}}} \cdot \alpha\right) & =i\left(\alpha_{\overline{\pi_{\varepsilon}}}\right)+i(\alpha) \\
i\left(\alpha^{\star}\right) & =i(\alpha),
\end{aligned}
$$

where $\overline{\alpha_{\pi_{\varepsilon}}^{\star}}$ denotes regular expressions that are not of the form $\alpha_{\pi_{\varepsilon}}^{\star}$. Clearly, the generating function for these expressions is $R_{\overline{\varepsilon^{\star}}, k}(z)=R_{k}(z)-z R_{\pi_{\varepsilon}, k}(z)$.

The cost generating function of the mergings, $I_{k}(z)$, can now be obtained from these equations by adding the contributions of each single one of them. These contributions can be computed as here exemplified for the contribution of the regular expressions of the form $\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\pi_{\varepsilon}}\right)$ :

$$
\begin{aligned}
\sum_{\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\pi_{\varepsilon}}\right)} i\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\pi_{\varepsilon}}\right) z^{\left|\left(\alpha_{\pi_{\varepsilon}}+\alpha_{\pi_{\varepsilon}}\right)\right|}= & z \sum_{\alpha_{\pi_{\varepsilon}}} \sum_{\alpha_{\pi_{\varepsilon}}}\left(i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\alpha_{\pi_{\varepsilon}}\right)+1\right) z^{\left|\alpha_{\pi_{\varepsilon}}\right|} z^{\left|\alpha_{\pi_{\varepsilon}}\right|} \\
= & z \sum_{\alpha_{\pi_{\varepsilon}}} \sum_{\alpha_{\pi_{\varepsilon}}}\left(i\left(\alpha_{\pi_{\varepsilon}}\right)+i\left(\alpha_{\pi_{\varepsilon}}\right)\right) z^{\left|\alpha_{\pi_{\varepsilon}}\right|} z^{\left|\alpha_{\pi_{\varepsilon}}\right|} \\
& +z \sum_{\alpha_{\pi_{\varepsilon}}} \sum_{\alpha_{\pi_{\varepsilon}}} z^{\left|\alpha_{\pi_{\varepsilon}}\right|} \mid z^{\left|\alpha_{\pi_{\varepsilon}}\right|} \\
= & 2 z I_{\pi_{\varepsilon}, k}(z) R_{\pi_{\varepsilon}, k}(z)+z R_{\pi_{\varepsilon}, k}(z)^{2},
\end{aligned}
$$

where $I_{\pi_{\varepsilon}, k}(z)$ is the generating function for the mergings coming from $\alpha_{\pi_{\varepsilon}}$.

Applying this technique to the remaining cases, we have

$$
\begin{aligned}
I_{k}(z)= & 2 z R_{\pi_{\varepsilon}, k}(z) I_{\varepsilon, k}(z)+z R_{\pi_{\varepsilon}, k}(z)^{2} \\
& +z R_{\pi_{\varepsilon}, k}(z) I_{\overline{\pi_{\varepsilon}}, k}(z)+z R_{\overline{\pi_{\varepsilon}}, k}(z) I_{\pi_{\varepsilon}, k}(z) \\
& +z R_{\overline{\pi_{\varepsilon}}, k}(z) I_{k}(z)+z R_{k}(z) I_{\overline{\pi_{\varepsilon}}, k}(z) \\
& +z^{2}\left(2 R_{\pi_{\varepsilon}, k}(z) I_{\pi_{\varepsilon}, k}(z)+R_{\pi_{\varepsilon}, k}(z)^{2}\right) \\
& +z R_{\pi_{\varepsilon}, k}(z) I_{\overline{\pi_{\varepsilon}^{*}}, k}(z)+z R_{\overline{\pi_{\varepsilon}^{*}}, k}(z) I_{\pi_{\varepsilon}, k}(z) \\
& +z R_{\overline{\pi_{\varepsilon}}, k}(z) I_{k}(z)+z R_{k}(z) I_{\overline{\pi_{\varepsilon}}, k}(z) \\
& +z I_{k}(z) .
\end{aligned}
$$

Using $R_{\overline{\pi_{\varepsilon}^{\star}}, k}(z)=R_{k}(z)-z R_{\pi_{\varepsilon}, k}(z), R_{\overline{\pi_{\varepsilon}}, k}(z)=R_{k}(z)-R_{\pi_{\varepsilon}, k}(z)$ and the same relation for $I_{k}(z)$, we obtain

$$
I_{k}(z)(1-z)=4 z R_{k}(z) I_{k}(z)+z R_{\pi_{\varepsilon}, k}(z)^{2}+z^{2} R_{\pi_{\varepsilon}, k}(z)^{2}
$$

From (2), we finally get

$$
\begin{equation*}
I_{k}(z)=\frac{\left(z+z^{2}\right) R_{\pi_{\varepsilon}, k}(z)^{2}}{\sqrt{\Delta_{k}(z)}} \tag{15}
\end{equation*}
$$

The asymptotic value of the coefficients of this generating function can now be computed using (11), from which one gets (for any $0<\delta<\frac{1}{2}$ )

$$
64 z^{2} R_{\pi_{\varepsilon}, k}(z)^{2}=a_{k}(z)+b(z)^{2}-2 b(z) \sqrt{a_{k}(z)}+o\left(\Delta_{k}(z)^{\delta}\right) .
$$

Since

$$
\frac{1}{\sqrt{\Delta_{k}(z)}}=\frac{1}{\sqrt{2-2 \rho_{k}} \sqrt{1-z / \rho_{k}}}+o\left(\frac{1}{\sqrt{1-z / \rho_{k}}}\right)
$$

Lemma 6 and Proposition 5, yield

$$
\begin{equation*}
\left[z^{n}\right] I_{k}(z) \sim \frac{1+\rho_{k}}{64} \frac{\left(a_{k}\left(\rho_{k}\right)+b\left(\rho_{k}\right)^{2}-2 b\left(\rho_{k}\right) \sqrt{a_{k}\left(\rho_{k}\right)}\right)}{\sqrt{\pi} \sqrt{2-2 \rho_{k}}} \rho_{k}^{-(n+1)} n^{-1 / 2} \tag{16}
\end{equation*}
$$

Table 1 exhibits the ratio between the approximation given by this computation and the actual coefficients of the power series of $I_{k}(z)$, for several values of $k$ and $n$.

From (3) and (16) one easily gets the following asymptotic estimate for the average number of mergings

$$
\begin{equation*}
\frac{\left[z^{n}\right] I_{k}(z)}{\left[z^{n}\right] R_{k}(z)} \sim \lambda_{k} n \tag{17}
\end{equation*}
$$

where

$$
\lambda_{k}=\frac{\left(1+\rho_{k}\right)}{16\left(1-\rho_{k}\right)}\left(a_{k}\left(\rho_{k}\right)+b\left(\rho_{k}\right)^{2}-2 b\left(\rho_{k}\right) \sqrt{a_{k}\left(\rho_{k}\right)}\right) .
$$

Table 1. Accuracy of the approximation.

| $n=$ | 10 | 20 | 50 | 100 | 200 | 400 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $k=2$ | 1.34 | 1.14 | 1.05 | 1.03 | 1.01 | 1.01 |
| $k=3$ | 1.35 | 1.12 | 1.05 | 1.02 | 1.01 | 1.01 |
| $k=5$ | 1.38 | 1.12 | 1.04 | 1.02 | 1.01 | 1.01 |
| $k=10$ | - | 1.13 | 1.04 | 1.02 | 1.01 | 1.01 |
| $k=20$ | - | - | 1.04 | 1.02 | 1.01 | 1.01 |
| $k=50$ | - | - | - | 1.02 | 1.01 | 1.01 |
| $k=100$ | - | - | - | - | 1.01 | 1.04 |

Using again the fact that $\lim _{k \rightarrow \infty} \rho_{k}=0, \lim _{k \rightarrow \infty} a_{k}\left(\rho_{k}\right)=9$ and $\lim _{k \rightarrow \infty} b\left(\rho_{k}\right)=1$, one gets that

$$
\lim _{k \rightarrow \infty} \lambda_{k}=\frac{1}{4}
$$

This means that, for a regular expression of size $n$, the average number of state mergings is, asymptotically, about $\frac{n}{4}$.

In order to obtain a lower bound for the reduction in the number of states of the $\mathcal{A}_{\text {pd }}$ automaton, as compared to the ones of the $\mathcal{A}_{\text {pos }}$ automaton, it is enough to compare the number of mergings for an expression $\alpha$ with the number of letters in $\alpha$. From (5) and (17) one gets

$$
\begin{equation*}
\frac{\left[z^{n}\right] I_{k}(z)}{\left[z^{n}\right] L_{k}(z)} \sim \frac{1-\rho_{k}}{4 k \rho_{k}^{2}} \lambda_{k}=\iota_{k} \tag{18}
\end{equation*}
$$

It is easy to see that

$$
\lim _{k \rightarrow \infty} \iota_{k}=\lim _{k \rightarrow \infty} \frac{1-\rho_{k}}{4 k \rho_{k}^{2}} \lambda_{k}=\frac{1}{2} .
$$

In other words, asymptotically, the average number of states of the $\mathcal{A}_{\mathrm{pd}}$ automaton is about one half of the number of states of the $\mathcal{A}_{\text {pos }}$ automaton, and about one quarter of the size of the corresponding regular expression, by (7). As shown in the last two columns of Table 2 the actual values are close to these limits already for small alphabets.

## 6. Comparison with Experimental Results

In order to compare our estimates with the actual number of states in a $\mathcal{A}_{\mathrm{pd}}$ automaton we ran some experiments.

We used the FAdo library [1,6], that includes algorithms for computing the Glushkov automaton and the partial derivatives automaton corresponding to a given regular expression. For the results to be statistically significant, regular expressions must be uniformly random generated. The FAdo library implements the recursive method described by Mairson [11] for the uniform random generation of contextfree languages. The random generator has as input a grammar and the size of the words to be generated. To obtain regular expressions uniformly generated in the

Table 2. Experimental results for uniform random generated regular expressions.

| $k$ | $\|\alpha\|$ | $\|\alpha\| \Sigma$ | $\left\|\delta_{\mathrm{pos}}\right\|$ | $\|\mathrm{PD}\|$ | $\left\|\delta_{\mathrm{pd}}\right\|$ | $\|\overline{\mathrm{PD}}\|$ | $\Gamma$ | $\frac{\|\alpha\|_{\Sigma}}{\alpha \mid}$ | $\lambda_{k}$ | $\iota_{k}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

size of the syntactic tree (i.e. parentheses not counted), a prefix notation version of the grammar (1) was used. For each size, $n$, samples of 1000 regular expressions were generated. Table 2 presents the average values obtained for $n \in\{1000,2000\}$ and $k \in\{2,3,5,10,20,30,50\}$, where $\Gamma=\frac{|\alpha|_{\Sigma-}|\mathrm{PD}|}{|\alpha|_{\Sigma}}$, and the two last columns give the asymptotic ratios obtained in (17) and (18) for the corresponding values of $k$.

As can be seen from the columns with bold entries, the asymptotic averages obtained with the analytic methods are very close to the values obtained experimentally. In general, even for small values of $n$, the ratio of the number of states of $\mathcal{A}_{\text {pd }}$ to the number of states of $\mathcal{A}_{\text {pos }}$ coincide (within an error of less than $3 \%$ ) with our (asymptotic) estimates. These results indicate that occurrences of $\varepsilon$ in the set of partial derivatives are the main reason for a smaller number of states in the $\mathcal{A}_{\text {pd }}$ automaton, when compared with the one in the $\mathcal{A}_{\text {pos }}$ automaton. This is supported by comparing the column containing the number of states of $\mathcal{A}_{\mathrm{pd}}(|\mathrm{PD}|)$ with the one containing those of its marked version $(|\overline{\mathrm{PD}}|)$.

## 7. Final Remarks

In this paper we studied, using analytic methods, the average number of states of partial derivative automata. We proved this number to be, on average, half the number of states when considering the Glushkov automata case. It is a subject for future research to study if an approach similar to the one applied here can be used to estimate the average number of transitions of $\mathcal{A}_{\text {pd }}$. According to Table 2, this number also seems to be half the number of transitions of $\mathcal{A}_{\text {pos }}$. At first sight, one
would expect that the use of alternative grammars for the generation of regular expressions, with less redundancy, such as the ones presented by Lee and Shallit [10], would lead to different results. However, experimental studies do not support this expectation, since they do not show significant differences from the results here presented.
