The Simpsons family tree

- ▶ We want a program that answers questions about the family.

The Simpsons family tree

To describe a family tree we need some facts:

- ▶ Homer is the father of Bart, Lisa and Maggie.
- ▶ Marge is their mother.

Some entities are mentioned here (Homer, Bart, Lisa, etc.). These are important concepts which will be represented as **constants**.

We also have relations such as “X is father of Y” and “X is mother of Y”. father and mother are also called **predicates**. In Prolog the above **facts** are represented as follows.

- ▶ We want a program that answers questions about the family.

Stating the facts!

In Prolog, the above facts are represented as follows:

```
father(homer,bart).  
father(homer,lisa).  
father(homer,maggie).
```

```
mother(marge,bart).  
mother(marge,lisa).  
mother(marge,maggie).
```

Note

- ▶ constants
- ▶ predicates
- ▶ period

Asking questions

We can ask questions such as (pose queries)

- ▶ *Who is the father of Bart?*

```
?-father(X,bart).
```

Type enter

```
X = homer
```

Note

- ▶ The answer is simply “Homer”
- ▶ The query is posed with a **variable** X
- ▶ We are asking is “*Is there an X such that X is father of bart?*”.
- ▶ The answer is “*yes, and the value of X is homer*”.

Asking questions

We can ask questions such as (pose queries)

- ▶ *Who are the offsprings of Marge?*

```
?-mother(marge,X).
```

```
X = bart;
```

```
X = lisa;
```

```
X = maggie
```

Note

- ▶ X can take multiple values
- ▶ mother(marge,X) is **true** for multiple values of X
- ▶ but we used **mother** instead of **offspring**...

Defining concepts

We have facts concerning the predicates **mother** and **father**.

- ▶ We can ask about offsprings by quering about **mother** and **father**.
- ▶ Nothing wrong, but I would like to have the concept **offspring**.
- ▶ Poor solution: write the facts!
- ▶ Good solution: define the concept **offspring** in general.

`offspring(X,Y):-mother(Y,X).`

`offspring(X,Y):-father(Y,X).`

Note

- ▶ We wrote two **rules**.
- ▶ Each one is a **logical implication** (`:-` represents \leftarrow).
- ▶ How to read each rule?

Defining concepts

We have facts concerning the predicates **mother** and **father**.

- ▶ We can ask about offsprings by querying about **mother** and **father**.
- ▶ Nothing wrong, but I would like to have the concept **offspring**.
- ▶ Poor solution: write the facts!
- ▶ Good solution: define the concept **offspring** in general.

Posing queries about **offspring**.

```
?-offspring(X,marge).
```

```
...
```

```
?-offspring(bart,X).
```

```
...
```

```
?-offspring(X,Y).
```

```
...
```

- ▶ How are these queries answered?

Defining concepts

Examples.

- ▶ Define the concept **son**.
- ▶ Define the concept **daughter**.
- ▶ Define the concept **parent**, in three different ways.
- ▶ Define the concept **sibling** of both sides.

Comparing Prolog terms

Defining the predicate **sibling/2**

```
sibling(X,Y):-  
    mother(M,X),mother(M,Y),  
    father(F,X),father(F,Y).
```

```
?-sibling(bart,X).
```

```
X = bart;
```

```
X = lisa;
```

```
X = maggie
```

We do not want Bart to be his own sibling...

Comparing Prolog terms

We need to state that X and Y are different objects

```
sibling(X,Y):-  
    mother(M,X),mother(M,Y),  
    father(F,X),father(F,Y),  
    not(X==Y).
```

- ▶ `not(X)` is true if X is false.
- ▶ `X==Y` is true if X and Y are the same objects.
- ▶ `X=Y` is true if X and Y are unifiable (and they unify).
- ▶ `X:=:Y` is true if X and Y are the same numerical (or expressions that result in the same numerical)

Unifying Prolog terms

Let us extend our “knowledge base” (the Prolog program) with more facts.

```
father(homer,bart).  
father(homer,maggie).  
father(abraham,herb).  
father(clancy,patty).
```

```
father(homer,lisa).  
father(abraham,homer).  
father(clancy,marge).  
father(clancy,selma).
```

```
mother(marge,bart).  
mother(marge,maggie).  
mother(mona,herb).  
mother(jackline,patty).  
mother(selma,ling).
```

```
mother(marge,lisa).  
mother(mona,homer).  
mother(jackline,marge).  
mother(jackline,selma).
```

Unifying Prolog terms

And define the predicate **grandfather/2**.

```
grandfather(X,Y):-father(X,A), father(A,Y).
```

```
grandfather(X,Y):-father(X,A), mother(A,Y).
```

In both clauses A is unified implicitly...

We can use explicit unification (without advantage here).

```
grandfather(X,Y):-father(X,A), father(B,Y), A=B.
```

```
grandfather(X,Y):-father(X,A), mother(B,Y), A=B.
```

Compound terms

Besides constants and variables, Prolog also has compound terms.
Let's write a program for arithmetics using logic only.

- ▶ The number zero is represented as 0.
- ▶ one as $s(0)$, two as $s(s(0))$ and so on.

s is a **functor** of arity 1, i.e. it has one argument.

How to define the predicate **sum/3** ?

```
sum(0,X,X).
```

```
sum(s(X),Y,s(Z)):-sum(X,Y,Z).
```

Compound terms

How to define the predicate **sum/3** ?

sum(0,X,X) .

sum(s(X),Y,s(Z)) :-**sum**(X,Y,Z) .

Calculating by infering.

?-**sum**(s(0),s(0),X),**sum**(X,X,Y),**sum**(X,Y,Z) .

X = s(s(0)),

Y = s(s(s(s(0)))) ,

Z = s(s(s(s(s(s(s(0)))))))

Vocabulary

- ▶ **term:** constant, variable or compound term.
 - ▶ a, adam, X, f(a), 23.
- ▶ terms are **ground** if they contain no variables.
 - ▶ adam is ground, X is not.
- ▶ a **substitution** is a set of pairs t/X , where t is a term and X is a variable.
- ▶ **father(adam,abel)** is an **instance** of **father(X,Y)** because there is a substitution θ that when applied to the more general term results in the more specific one.
 - ▶ but not of **father(X,X)**.

Vocabulary

- ▶ a **logic program** is a finite set of clauses.
- ▶ a **clause** or rule has the form
$$A \leftarrow B_1, B_2, \dots, B_k. \quad k \geq 0$$
where A and B_i are **literals**.
- ▶ a clause has the **head** and **body**
- ▶ when $k = 0$ the clause is a **fact** and is simply A .
- ▶ a **query** has the form $?-A_1, A_2, \dots, A_n$.
 - ▶ A_i are also called **goals**.

Defining concepts

Examples.

- ▶ Define the concept **grandparent**.
- ▶ Define the concept **uncle**.
- ▶ Define the concept **ancestor**.
- ▶ Define the concept **sibling1** of exactly one side.
