

Steel stacking

A problem in inventory management in the steel industry

João Pedro Pedroso

International Symposium on Mathematics of Logistics
TUMSAT, Japan, November 2011

Part of the presentation concerns
joint work with **Rui Rei** and **Mikio Kubo**.

Informal problem description

Context

A steel producer has a warehouse where the final product is stocked

- large steel bars enter the warehouse when production finishes
- bars leave the warehouse on trucks or ships for transporting them to the final customer
- there is a crane in the warehouse, which moves the bars one at a time
- the warehouse has p different places
- each place can be empty, or keep a stack of steel bars

Informal problem description

Assumptions

- capacity of the stacks is infinite
- no delays on crane movements
- crane can move only one item at a time
- only the item on the top of the stack can be moved
- item on top of each stack may have to be relocated (*reshuffling*)

Objective

- minimize the number of movements made by the crane

Steel stacking

Steel stacking

Data

$p \in \mathbb{N}$	number of stacks on the warehouse
$n \in \mathbb{N}$	number of items
$R_i \in \mathbb{N}, i = 1, \dots, n$	release dates
$D_i \in \mathbb{N}, i = 1, \dots, n$	delivery dates

Steel stacking

Constraints

- crane can move only the item on top of the stack
- release and delivery dates must be satisfied
- the valid movements depend on R , D , and on the choices made up to the moment.

Solution representation

List of movements from a stack (o) to another (d)

$$M = [(o_1, d_1), \dots, (o_k, d_k)]$$

- $0 \leq o_i \leq p$ and $1 \leq d_i \leq p + 1$
- stack 0 represents the production facility
- stack $p + 1$ represents the customer track/ship.
- we want to minimize the number of movements (size of M)

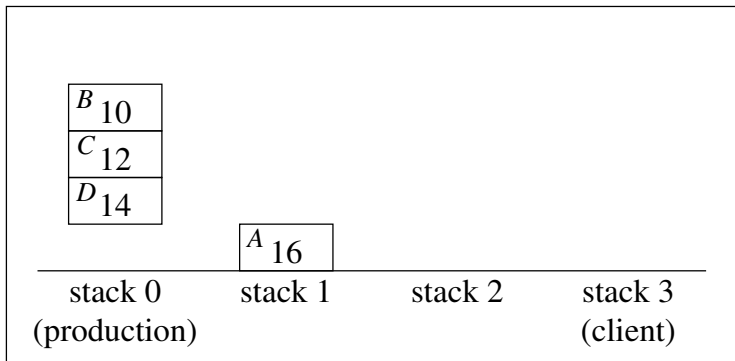

Example – step 1

Movements:

[]

Example – step 1

Movements:

[(0, 1)]

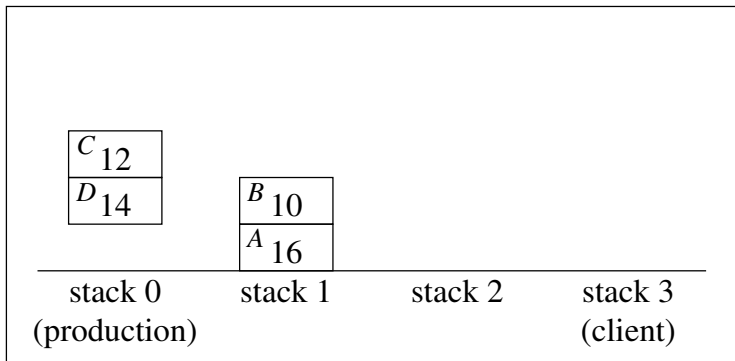

Example – step 2

Movements:

$[(0, 1)]$

Example – step 2

Movements:

$[(0, 1), (0, 1)]$

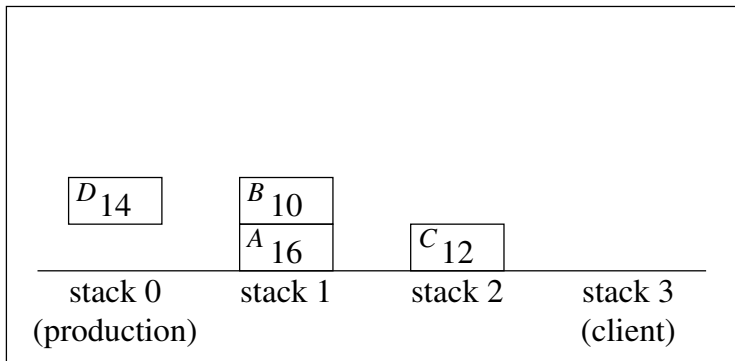

Example – step 3

Movements:

$[(0, 1), (0, 1)]$

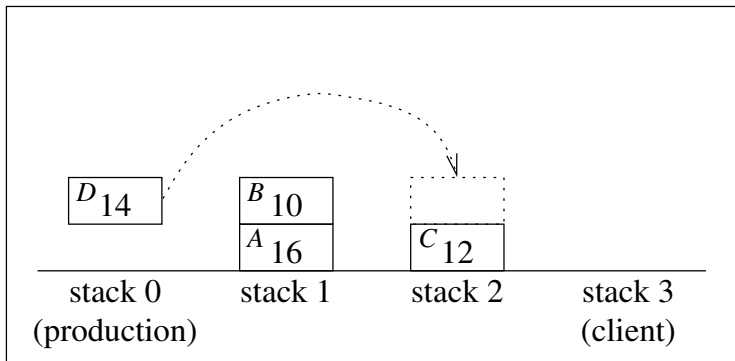

Example – step 3

Movements:

$[(0, 1), (0, 1), (0, 2)]$

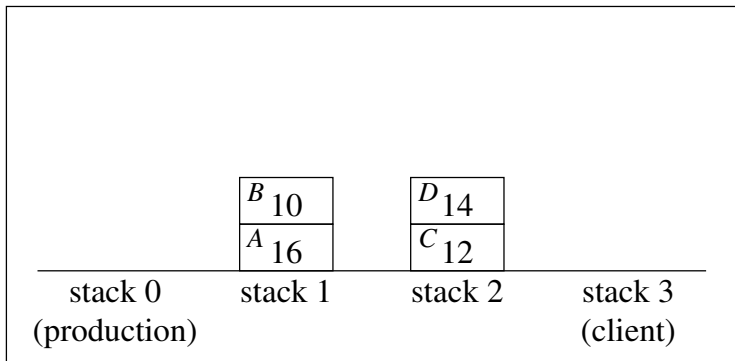

Example – step 4

Movements:

$[(0, 1), (0, 1), (0, 2)]$

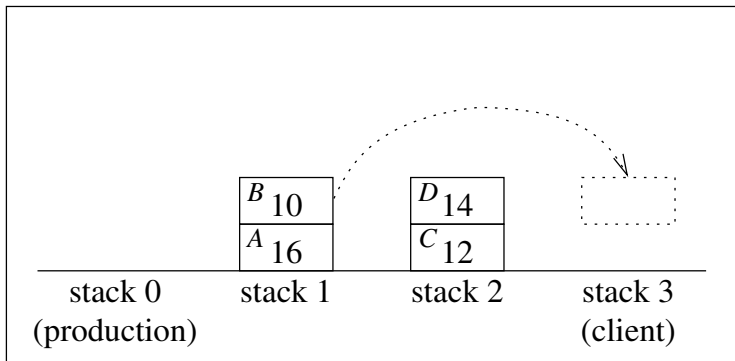

Example – step 4

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2)]$

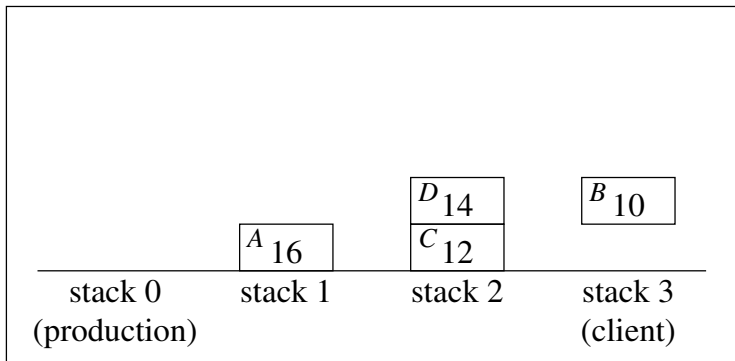

Example – step 5

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2)]$

Example – step 5

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2), (1, 3)]$

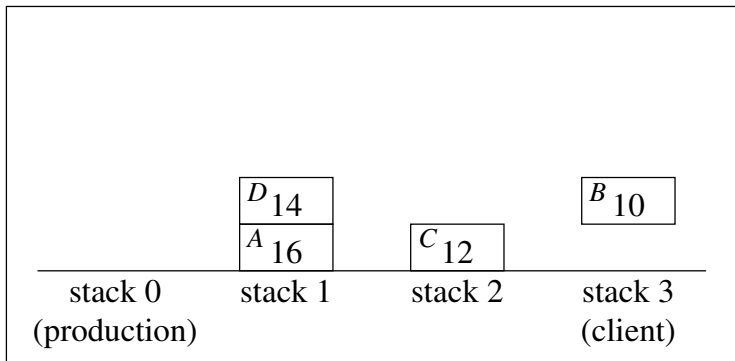

Example – step 6

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2), (1, 3)]$

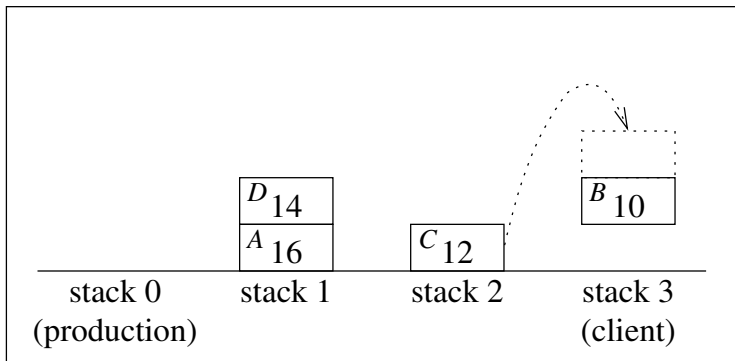

Example – step 6

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2), (1, 3), (2, 1)]$

Example – step 7

Movements:

$[(0, 1), (0, 1), (0, 2), (0, 2), (1, 3), (2, 1), \rightarrow (2, 3), (1, 3), (1, 3)]$

This information is complemented with release and due dates.

Solution representation: MIP

If we want to solve the problem with standard optimization tools:
MIP formulation:

Sets

$T \in \mathbb{N}$ – time horizon (the number of periods in the model)

$N \in \mathbb{N}$ – number of items

$W \in \mathbb{N}$ – the number of stacks in the warehouse (warehouse width).

$H \in \mathbb{N}$ – the maximum number of items that can be in a stack at any given instant (warehouse height).

$R \in \mathbb{R}^N$ – item release dates (R_i denotes the release date of item i).

$D \in \mathbb{R}^N$ – item due dates (D_i denotes the due date of item i).

Solution representation: MIP

Problem: number of **periods** that have to be considered

Worst case: $T = 2N + \sum_{n=1}^{N-1} n$

Solution representation: MIP

MIP formulation

Variables

x_{ijnt} – 1 if item n is released into position (i, j) at period t

y_{ijklnt} – 1 if item n is relocated from position (i, j) into (k, l) at period t

z_{ijnt} – 1 if item n is delivered from position (i, j) at period t

a_{nt} – 1 if item n has not entered the warehouse yet at period t

b_{ijnt} – 1 if item n is in row j of stack i at period t

c_{nt} – 1 if item n has already left the warehouse at period t

Solution representation: branch-and-bound

Branch-and-bound

- When an item is released/relocated:
 - Check all stacks where it can be placed
 - Create a branch for each of them
- When an item is delivered from top: move without branching.

Contents

- 1 Problem description
- 2 **Solution methods**
 - MIP solution
 - Branch-and-bound
 - Simulation-based optimization
- 3 Problem variants
 - More general structures
 - Limited movements
 - Dynamics
 - Other objectives
- 4 Conclusions

MIP

- formulate the problem, create model
- read an instance
- send it to a solver

Branch-and-bound method

- (1) create empty queue Q
- (2) push root node into Q
- (3) **while** Q is not empty
- (4) $\mu \leftarrow$ pop a node from Q
- (5) $i \leftarrow$ item to be placed next on node μ
- (6) **foreach** stack s where i can be placed
- (7) $\mu' \leftarrow$ a copy of node μ
- (8) place item i in stack s on node μ'
- (9) execute deliveries from top of stacks in μ'
- (10) **if** μ' is a leaf node
- (11) check if μ' contains a better solution
- (12) push node μ' into Q

Discrete event simulation

- type of simulation used on systems where the state variations are discrete
- computationally “inexpensive”

In our case:

- each simulation run involves some randomness: stack for each item is selected randomly from list of candidates
- different runs lead to different solutions
- at the end, choose the best run (a large number of runs may be required for obtaining good results)
- several stacking strategies (heuristics) can be used and tested

Simulation strategy:

Heuristics for choosing a stack for an item are applied

- 1 on arrival of an item
- 2 when moving an item from the top, to reach another below it (*reshuffling*).

Processing order

- delivery has precedence over stacking released items
- “simultaneous” releases are processed by inverse delivery date
- “simultaneous” deliveries are processed from top to bottom of the stack

“Simultaneous” deliveries:

No specified order on simultaneous deliveries:

- ① $\{C, D\} : s_2 \rightarrow s_1$
- ② $E : s_2 \rightarrow \text{client}$
- ③ $\{D, C, A\} : s_1 \rightarrow s_2$
- ④ $B : s_1 \rightarrow \text{client}$

$\hookrightarrow 7$ movements

Deliveries processed by item depth:

- ① $A : s_1 \rightarrow s_2$
- ② $B : s_1 \rightarrow \text{client}$
- ③ $\{A, C, D\} : s_2 \rightarrow s_1$
- ④ $E : s_2 \rightarrow \text{client}$

$\hookrightarrow 6$ movements

Positioning heuristics

When placing an item

- each position (i.e., each stack) is assigned a value, according to some rules
- construct a **candidate list** of positions with best classification (depends on the heuristics used)
- from this list, randomly choose one for placing the item

Heuristics: Optimize flexibility

- we define **flexibility** of a position as the *maximum number of items* with different delivery dates that can be stacked, *without causing an inversion*
- candidate stacks for an item are those which:
 - maximize flexibility and cause no inversion
 - minimize flexibility, if an inversion is unavoidable

Simulation-based optimization

- For this stacking heuristics:
 - do N independent simulation runs
 - choose the run that lead to less crane movements
- For each of the N runs:
 - for each item, choose a stack according to the selected heuristics
 - continue processing item releases and deliveries, until having all items delivered
 - return the number of movements required, and the corresponding movement list

Contents

 - MIP solution
 - Branch-and-bound
 - Simulation-based optimization
- 3 Problem variants**
 - More general structures
 - Limited movements
 - Dynamics
 - Other objectives
- 4 Conclusions

Problem variants

There are many variants of the problem with practical interest:

- 1 stacks are replaced by more general structures, such as double-ended queues; this allows modeling *e.g.* cases where items are placed in a horizontal configuration, with access from two ends;
- 2 crane movements are limited, and thus the number of stacks that can be reached from a given position is limited;
- 3 placement in certain stacks limits crane movements, *i.e.*, the graph of connections is dynamically changed when items are placed;
- 4 crane movements induce significant delays, making the assumption of immediate delivery unviable;
- 5 other objectives.

More general structures

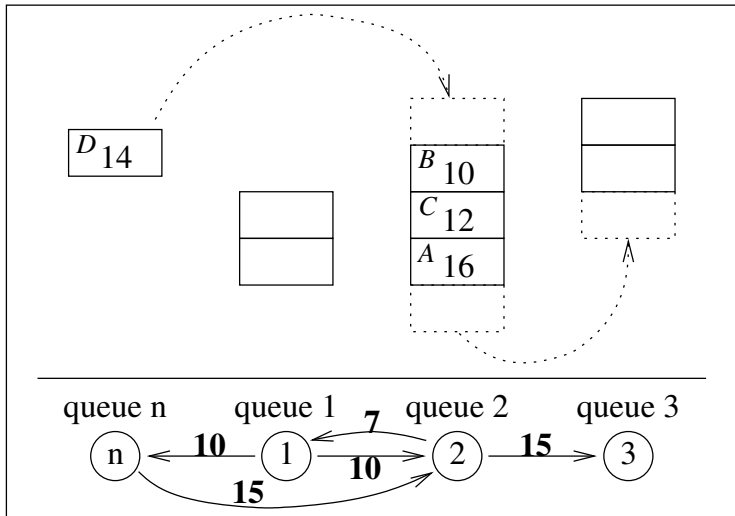

E.g., double ended queues

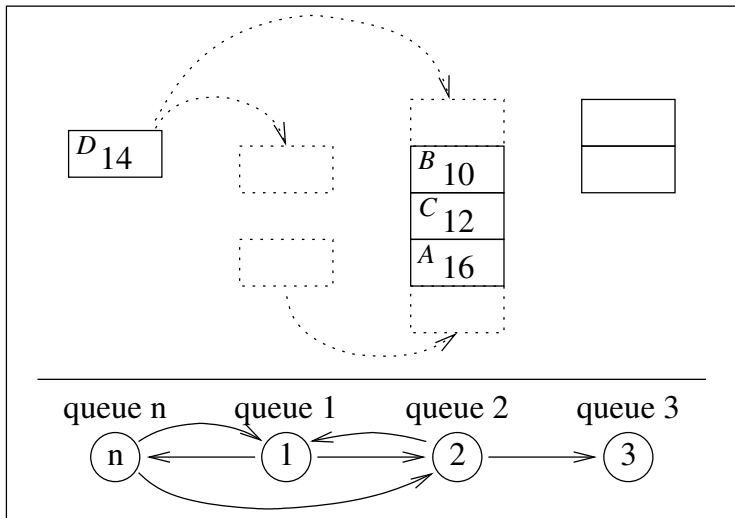

Limited movements

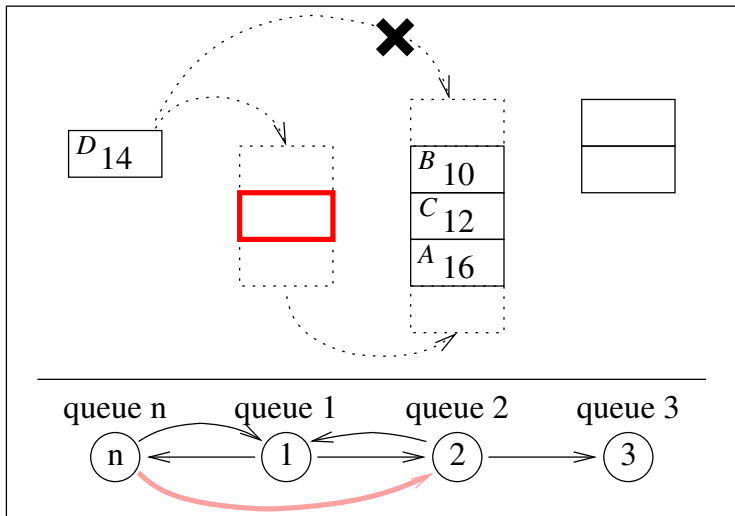

Dynamics

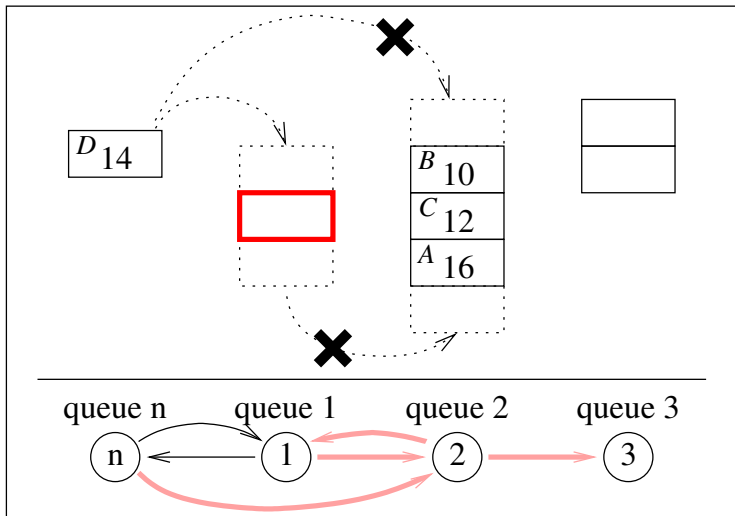

Dynamics: allowed movements change 1

Dynamics: allowed movements change 2

Dynamics: allowed movements change 3

Dynamics: times change

Other objectives

Another interesting variant:

- 1 minimize time of service of track/ship;
- 2 items are rearranged **before** track of ship arrive;
- 3 aim: having the **minimum number of movements** for loading the track/ship;
- 4 in some variants: more than one item may be moved at the same time.

Conclusions

- Problem tackled: difficult (decision in one step may have consequences much later).
- For tackling it:
 - MIP model;
 - Specialized branch-and-bound;
 - Simulation-based optimization.
- Problem has many interesting variants.
- Dynamics: configuration may change upon decisions taken.
- Modeling issues: language for formalizing problem description.
- New solution approaches: finite state automata.
