Declarative Aspects and Applications of Multicore Programming

# Why Parallelism in Prolog?

## Efficient sequential implementations

- There are many efficient sequential implementations of Prolog, mostly based on the **Warren Abstract Machine (WAM)**.

## Potential for implicit parallelism

- Prolog programs **naturally exhibit implicit parallelism**, thus **freeing** the programmers from the task of **explicitly** identifying it.
- This makes parallel logic programming **as easy as** logic programming.

# Implicit Parallelism in Prolog

## And-parallelism

- is the simultaneous evaluation of the several Prolog subgoals in the body of a clause.

```
path(X,Z) :- path(X,Y), edge(Y,Z).
```

# Implicit Parallelism in Prolog

## And-parallelism

- is the simultaneous evaluation of the several Prolog subgoals in the body of a clause.

```
path(X,Z) :- path(X,Y), edge(Y,Z).
```

## Or-parallelism

- is the simultaneous evaluation of a Prolog goal against all the alternative predicate clauses that match that goal.

```
path(X,Z) :- path(X,Y), edge(Y,Z).
```

```
path(X,Z) :- edge(X,Z).
```

- The least complexity of or-parallelism (alternative matching clauses are independent of each other) makes or-parallel models **more attractive** and **more successful** at a first step.

# Or-Parallelism: Implementation Challenges

## Multiple bindings

- How to efficiently represent the multiple bindings for variables shared by the parallel execution of alternative clauses.

- Private areas to store the bindings for each branch are required:
  - ▶ **Binding arrays**
  - ▶ **Environment copying**

# Or-Parallelism: Implementation Challenges

## Scheduling

- Achieving the necessary cooperation, synchronization and concurrent access to shared data structures among several workers during their execution is a difficult task.
- A parallel Prolog system is no exception as the parallelism that Prolog programs exhibit is usually highly irregular:
  - ▶ **Topmost dispatching** or **bottommost dispatching**.
  - ▶ **Dynamic sharing** or **static sharing** (stack splitting).

# Our Goal

## Stack splitting on multicores

- Design and implement static sharing, namely **stack splitting**, in the **YapOr system**.
- Benefit from prior research on the development of the YapOr system and extend it to efficiently support two work sharing stack splitting models, namely **vertical splitting** and **half splitting**, on multicore architectures.

# The YapOr System

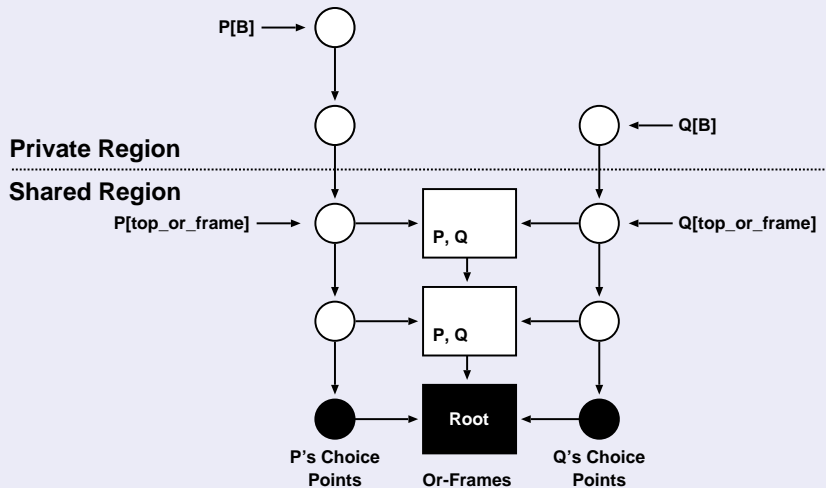

## Execution Model

- YapOr is based on the **environment copying model**:
  - ▶ Each worker maintains a **separated copy** of its environment.
  - ▶ Sharing is done by **copying the execution stacks** between workers.
- YapOr's scheduler is based on **bottommost dispatching** and **dynamic sharing**.
  - ▶ Synchronization is mostly needed at work sharing operations to ensure that each alternative is **explored only once**.
  - ▶ Shared nodes are represented by **or-frames**, a data structure that workers must access to obtain the untried alternatives, point in which **mutual exclusion** is enforced.

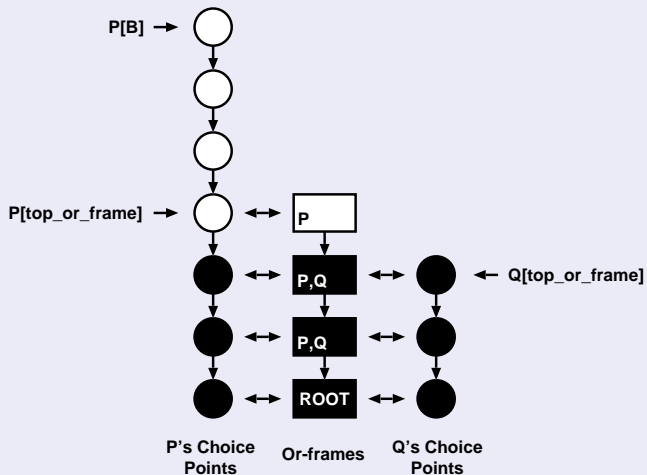

# The YapOr System

## Data structures

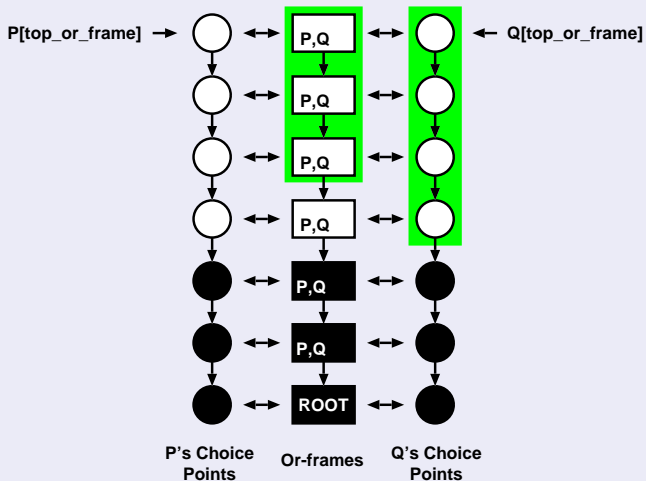

# Environment Copying

## Before sharing

# Environment Copying

## After sharing

# Stack Splitting

## General ideas

- Introduced to target **distributed memory architectures**.
- Aiming to **avoid the mutual exclusion requirements** when accessing shared branches of the search tree.
- Defines a work sharing strategy in which all available work is divided **in two fully independent parts**.
- The splitting is such that both workers can continue executing its branch of computation **independently**, without any need for further synchronization.

# Stack Splitting

## Vertical splitting

(a) before sharing

(b) after sharing

# Stack Splitting

## Half splitting

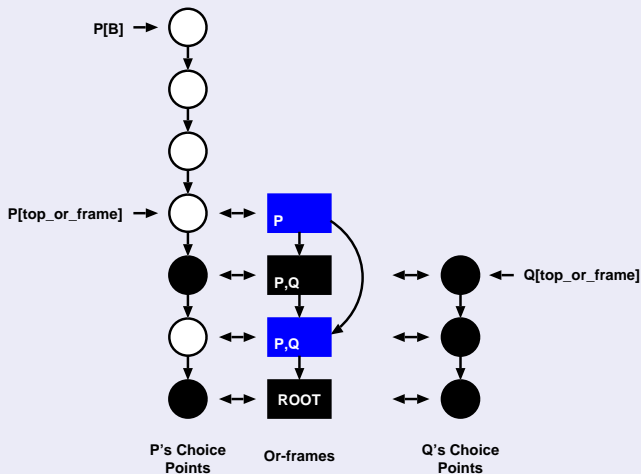

(a) before sharing

(b) after sharing

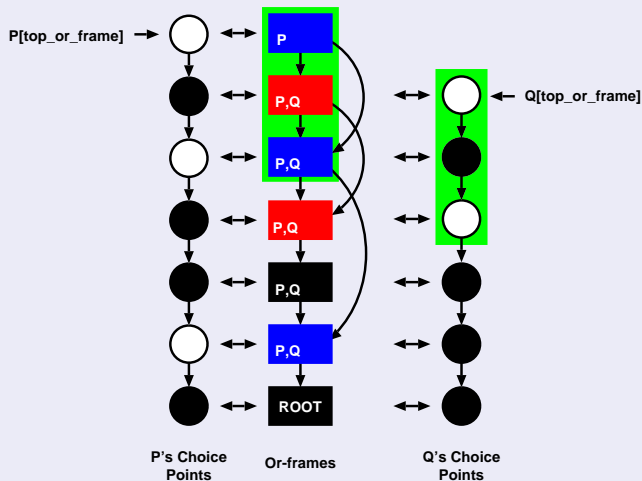

# Vertical Splitting

## Before sharing

# Vertical Splitting

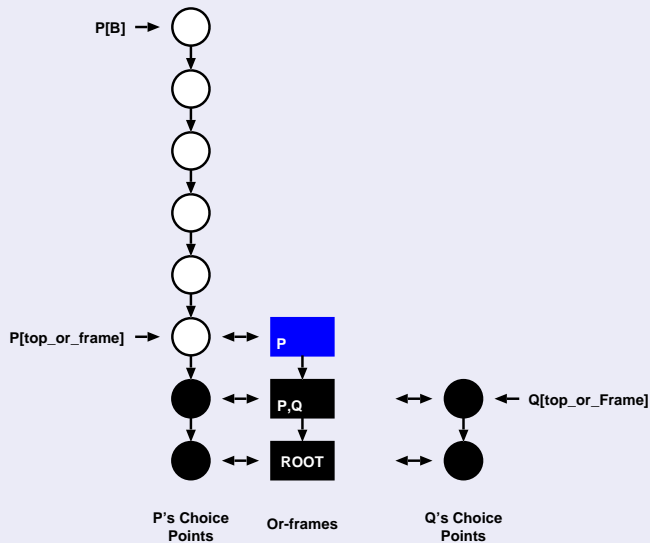

## After sharing

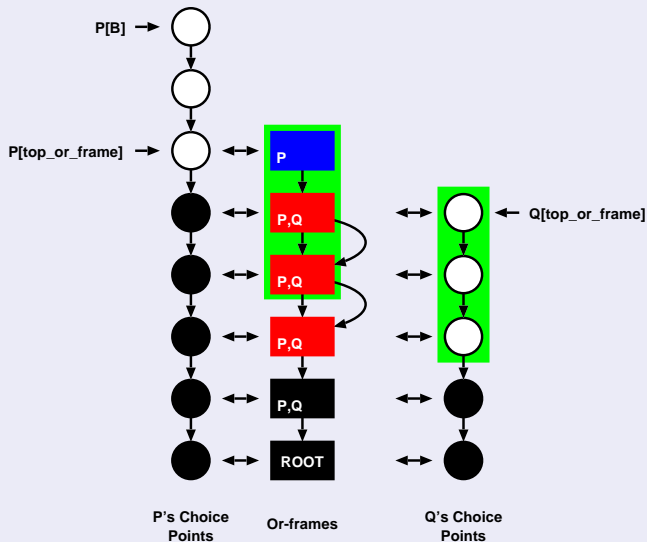

# Half Splitting

## Before sharing

# Half Splitting

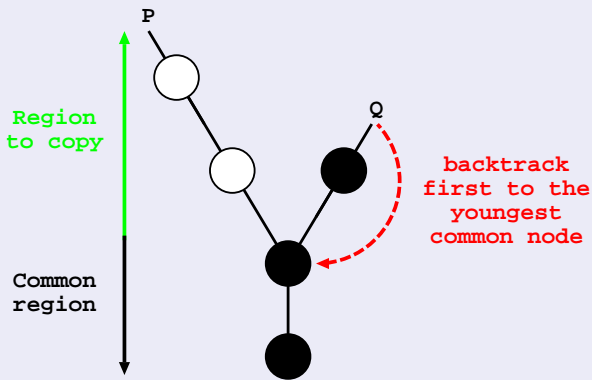

After sharing

# Incremental Copy

## General idea

- Aims to **minimize the amount of data** copied between P and Q.
- It copies only the **state difference** between workers P and Q.

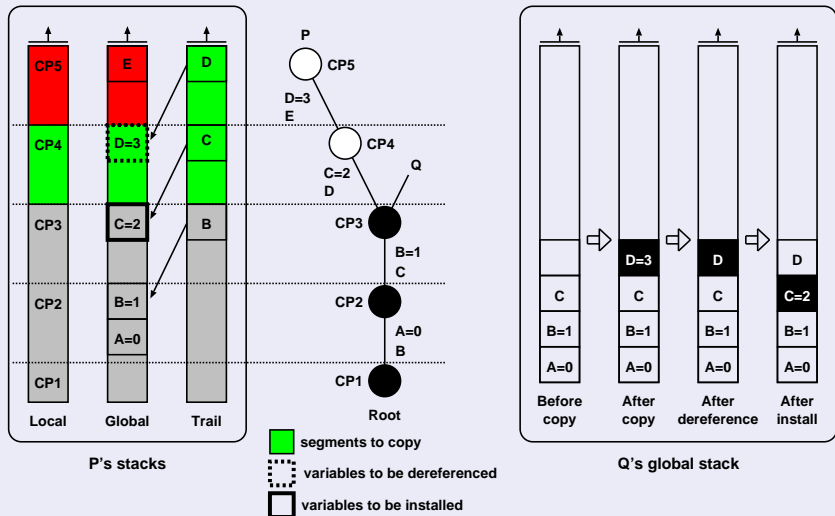

# Incremental Copy

## Copy ranges

# Incremental Copy

## Dereference phase

# Experimental Results

## Environment

- A machine with 4 AMD Six-Core Opteron TM 8425 HE (2100 MHz) chips (24 cores in total) and 64 (4x16) GB of DDR-2 667MHz RAM.
- Running Linux kernel 2.6.31.5-127 64 bits with Yap Prolog 6.2.0.
- All benchmarks find all the solutions by simulating an automatic failure whenever a new solution is found.
- Each benchmark was executed 20 times and the results are the average of those 20 executions.

# Experimental Results

## Cost of the parallel models (1 worker)

# Experimental Results

## Overall average analysis

# Conclusions and Further Work

## Conclusions

- We have presented the design and implementation of two stack splitting models in the YapOr system.
- Although stack splitting was proposed for distributed memory, our results show that it is equally suitable for shared memory machines:
  - ▶ In many benchmarks, we achieved **speedups above 20 on 24 cores**.
  - ▶ Vertical splitting overall performance **close to original YapOr**.
  - ▶ Half splitting performed **better in 4 of 10 benchmarks**.
  - ▶ Incremental copy **clearly benefits performance**.

# Conclusions and Further Work

## Further Work

- Implementation of **alternative** stack splitting strategies:
  - ▶ Horizontal splitting.
  - ▶ Diagonal splitting.
- Combining all models for supporting **clusters of multicores**:
  - ▶ Different **teams** should be assigned to different **cluster nodes** and share work performing **stack splitting**.
  - ▶ A team of workers should run on shared memory and **workers inside a team** can distribute work using **environment copying** or **stack splitting**.
